

# INTERPOLATION OF $\kappa$ -COMPACTNESS AND PCF

ISTVÁN JUHÁSZ AND ZOLTÁN SZENTMIKLÓSSY

ABSTRACT. We call a topological space  $\kappa$ -compact if every subset of size  $\kappa$  has a complete accumulation point in it. Let  $\Phi(\mu, \kappa, \lambda)$  denote the following statement:  $\mu < \kappa < \lambda = \text{cf}(\lambda)$  and there is  $\{S_\xi : \xi < \lambda\} \subset [\kappa]^\mu$  such that  $|\{\xi : |S_\xi \cap A| = \mu\}| < \lambda$  whenever  $A \in [\kappa]^{<\kappa}$ . We show that if  $\Phi(\mu, \kappa, \lambda)$  holds and the space  $X$  is both  $\mu$ -compact and  $\lambda$ -compact then  $X$  is  $\kappa$ -compact as well. Moreover, from PCF theory we deduce  $\Phi(\text{cf}(\kappa), \kappa, \kappa^+)$  for every singular cardinal  $\kappa$ . As a corollary we get that a linearly Lindelöf and  $\aleph_\omega$ -compact space is uncountably compact, that is  $\kappa$ -compact for all uncountable cardinals  $\kappa$ .

We start by recalling that a point  $x$  in a topological space  $X$  is said to be a *complete accumulation point* of a set  $A \subset X$  iff for every neighbourhood  $U$  of  $x$  we have  $|U \cap A| = |A|$ . We denote the set of all complete accumulation points of  $A$  by  $A^\circ$ .

It is well-known that a space is compact iff every infinite subset has a complete accumulation point. This justifies to call a space  $\kappa$ -compact if every subset of cardinality  $\kappa$  in it has a complete accumulation point. Now, let  $\kappa$  be a singular cardinal and  $\kappa = \sum\{\kappa_\alpha : \alpha < \text{cf}(\kappa)\}$  with  $\kappa_\alpha < \kappa$  for each  $\alpha < \text{cf}(\kappa)$ . Clearly, if a space  $X$  is both  $\kappa_\alpha$ -compact for all  $\alpha < \text{cf}(\kappa)$  and  $\text{cf}(\kappa)$ -compact then  $X$  is  $\kappa$ -compact as well. This trivial "extrapolation" property of  $\kappa$ -compactness (for singular  $\kappa$ ) implies that in the above characterization of compactness one may restrict to subsets of regular cardinality.

The aim of this note is to present a new "interpolation" result on  $\kappa$ -compactness, i.e. one in which  $\mu < \kappa < \lambda$  and we deduce  $\kappa$ -compactness of a space from its  $\mu$ - and  $\lambda$ -compactness. Again, this works for singular cardinals  $\kappa$  and the proof uses non-trivial results from Shelah's PCF theory.

---

*Key words and phrases.* complete accumulation point,  $\kappa$ -compact space, linearly Lindelöf space, PCF theory.

Research on this paper was supported by OTKA grants no. 61600 and 68262.

**Definition 1.** Let  $\kappa, \lambda, \mu$  be cardinals, then  $\Phi(\mu, \kappa, \lambda)$  denotes the following statement:  $\mu < \kappa < \lambda = \text{cf}(\lambda)$  and there is  $\{S_\xi : \xi < \lambda\} \subset [\kappa]^\mu$  such that  $|\{\xi : |S_\xi \cap A| = \mu\}| < \lambda$  whenever  $A \in [\kappa]^{<\kappa}$ .

As we can see from our next theorem, this property  $\Phi$  yields the promised interpolation result for  $\kappa$ -compactness.

**Theorem 2.** *Assume that  $\Phi(\mu, \kappa, \lambda)$  holds and the space  $X$  is both  $\mu$ -compact and  $\lambda$ -compact. Then  $X$  is  $\kappa$ -compact as well.*

*Proof.* Let  $Y$  be any subset of  $X$  with  $|Y| = \kappa$  and, using  $\Phi(\mu, \kappa, \lambda)$ , fix a family  $\{S_\xi : \xi < \lambda\} \subset [Y]^\mu$  such that  $|\{\xi : |S_\xi \cap A| = \mu\}| < \lambda$  whenever  $A \in [Y]^{<\kappa}$ . Since  $X$  is  $\mu$ -compact we may then pick a complete accumulation point  $p_\xi \in S_\xi^\circ$  for each  $\xi < \lambda$ .

Now we distinguish two cases. If  $|\{p_\xi : \xi < \lambda\}| < \lambda$  then the regularity of  $\lambda$  implies that there is  $p \in X$  with  $|\{\xi < \lambda : p_\xi = p\}| = \lambda$ . If, on the other hand,  $|\{p_\xi : \xi < \lambda\}| = \lambda$  then we can use the  $\lambda$ -compactness of  $X$  to pick a complete accumulation point  $p$  of this set. In both cases the point  $p \in X$  has the property that for every neighbourhood  $U$  of  $p$  we have  $|\{\xi : |S_\xi \cap U| = \mu\}| = \lambda$ .

Since  $S_\xi \cap U \subset Y \cap U$ , this implies using  $\Phi(\mu, \kappa, \lambda)$  that  $|Y \cap U| = \kappa$ , hence  $p$  is a complete accumulation point of  $Y$ , hence  $X$  is indeed  $\kappa$ -compact.  $\square$

Our following result implies that if  $\Phi(\mu, \kappa, \lambda)$  holds then  $\kappa$  must be singular.

**Theorem 3.** *If  $\Phi(\mu, \kappa, \lambda)$  holds then we have  $\text{cf}(\mu) = \text{cf}(\kappa)$ .*

*Proof.* Assume that  $\{S_\xi : \xi < \lambda\} \subset [\kappa]^\mu$  witnesses  $\Phi(\mu, \kappa, \lambda)$  and fix a strictly increasing sequence of ordinals  $\eta_\alpha < \kappa$  for  $\alpha < \text{cf}(\kappa)$  that is cofinal in  $\kappa$ . By the regularity of  $\lambda > \kappa$  there is an ordinal  $\xi < \lambda$  such that  $|S_\xi \cap \eta_\alpha| < \mu$  holds for each  $\alpha < \text{cf}(\kappa)$ . But this  $S_\xi$  must be cofinal in  $\kappa$ , hence from  $|S_\xi| = \mu$  we get  $\text{cf}(\mu) \leq \text{cf}(\kappa) \leq \mu$ .

Now assume that we had  $\text{cf}(\mu) < \text{cf}(\kappa)$  and set  $|S_\xi \cap \eta_\alpha| = \mu_\alpha$  for each  $\alpha < \text{cf}(\kappa)$ . Our assumptions then imply  $\mu^* = \sup\{\mu_\alpha : \alpha < \text{cf}(\kappa)\} < \mu$  as well as  $\text{cf}(\kappa) < \mu$ , contradicting that  $S_\xi = \cup\{S_\xi \cap \eta_\alpha : \alpha < \text{cf}(\kappa)\}$  and  $|S_\xi| = \mu$ . This completes our proof.  $\square$

According to theorem 3 the smallest cardinal  $\mu$  for which  $\Phi(\mu, \kappa, \lambda)$  may hold for a given singular cardinal  $\kappa$  is  $\text{cf}(\kappa)$ . Our main result says that this actually does happen with the natural choice  $\lambda = \kappa^+$ .

**Theorem 4.** *For every singular cardinal  $\kappa$  we have  $\Phi(\text{cf}(\kappa), \kappa, \kappa^+)$ .*

*Proof.* We shall make use of the following fundamental result of Shelah from his PCF theory: There is a strictly increasing sequence of length

$\text{cf}(\kappa)$  of regular cardinals  $\kappa_\alpha < \kappa$  cofinal in  $\kappa$  and such that in the product

$$\mathbb{P} = \prod \{\kappa_\alpha : \alpha < \text{cf}(\kappa)\}$$

there is a scale  $\{f_\xi : \xi < \kappa^+\}$  of length  $\kappa^+$ . (This is Main Claim 1.3 on p. 46 of [2].)

Spelling it out, this means that the  $\kappa^+$ -sequence  $\{f_\xi : \xi < \kappa^+\} \subset \mathbb{P}$  is increasing and cofinal with respect to the partial ordering  $<^*$  of eventual dominance on  $\mathbb{P}$ . Here for  $f, g \in \mathbb{P}$  we have  $f <^* g$  iff there is  $\alpha < \text{cf}(\kappa)$  such that  $f(\beta) < g(\beta)$  whenever  $\alpha \leq \beta < \text{cf}(\kappa)$ .

Now, to show that this implies  $\Phi(\text{cf}(\kappa), \kappa, \kappa^+)$ , we take the set  $H = \cup\{\{\alpha\} \times \kappa_\alpha : \alpha < \text{cf}(\kappa)\}$  as our underlying set. Note that then  $|H| = \kappa$  and every function  $f \in \mathbb{P}$ , construed as a set of ordered pairs (or in other words: identified with its graph) is a subset of  $H$  of cardinality  $\text{cf}(\kappa)$ .

We claim that the scale sequence  $\{f_\xi : \xi < \kappa^+\} \subset [H]^{\text{cf}(\kappa)}$  witnesses  $\Phi(\text{cf}(\kappa), \kappa, \kappa^+)$ . Indeed, let  $A$  be any subset of  $H$  with  $|A| < \kappa$ . We may then choose  $\alpha < \text{cf}(\kappa)$  in such a way that  $|A| < \kappa_\alpha$ . Clearly, then there is a function  $g \in \mathbb{P}$  such that we have  $A \cap (\{\beta\} \times \kappa_\beta) \subset \{\beta\} \times g(\beta)$  whenever  $\alpha \leq \beta < \text{cf}(\kappa)$ . Since  $\{f_\xi : \xi < \kappa^+\}$  is cofinal in  $\mathbb{P}$  w.r.t.  $<^*$ , there is a  $\xi < \kappa^+$  with  $g <^* f_\xi$  and obviously we have  $|A \cap f_\xi| < \text{cf}(\kappa)$  whenever  $\xi \leq \eta < \kappa^+$ .  $\square$

Note that the above proof actually establishes the following more general result: If for some increasing sequence of regular cardinals  $\{\kappa_\alpha : \alpha < \text{cf}(\kappa)\}$  that is cofinal in  $\kappa$  there is a scale of length  $\lambda = \text{cf}(\lambda)$  in the product  $\prod \{\kappa_\alpha : \alpha < \text{cf}(\kappa)\}$  then  $\Phi(\text{cf}(\kappa), \kappa, \lambda)$  holds.

Before giving some further interesting application of the property  $\Phi(\mu, \kappa, \lambda)$ , we present a result that enables us to "lift" the first parameter  $\text{cf}(\kappa)$  in theorem 4 to higher cardinals.

**Theorem 5.** *If  $\Phi(\text{cf}(\kappa), \kappa, \lambda)$  holds for some singular cardinal  $\kappa$  then we also have  $\Phi(\mu, \kappa, \lambda)$  whenever  $\text{cf}(\kappa) < \mu < \kappa$  with  $\text{cf}(\mu) = \text{cf}(\kappa)$ .*

*Proof.* Let us put  $\text{cf}(\kappa) = \varrho$  and fix a strictly increasing and cofinal sequence  $\{\kappa_\alpha : \alpha < \varrho\}$  of cardinals below  $\kappa$ . We also fix a partition of  $\kappa$  into disjoint sets  $\{H_\alpha : \alpha < \varrho\}$  with  $|H_\alpha| = \kappa_\alpha$  for each  $\alpha < \varrho$ .

Let us now choose a family  $\{S_\xi : \xi < \lambda\} \subset [\kappa]^\varrho$  that witnesses  $\Phi(\text{cf}(\kappa), \kappa, \lambda)$ . Since  $\lambda$  is regular, we may assume without any loss of generality that  $|H_\alpha \cap S_\xi| < \varrho$  holds for every  $\alpha < \varrho$  and  $\xi < \lambda$ . Note that this implies  $|\{\alpha : H_\alpha \cap S_\xi \neq \emptyset\}| = \varrho$  for each  $\xi < \lambda$ .

Now take a cardinal  $\mu$  with  $\text{cf}(\mu) = \varrho < \mu < \kappa$  and fix a strictly increasing and cofinal sequence  $\{\mu_\alpha : \alpha < \varrho\}$  of cardinals below  $\mu$ .

To show that  $\Phi(\mu, \kappa, \lambda)$  is valid, we may use as our underlying set  $S = \cup\{H_\alpha \times \mu_\alpha : \alpha < \varrho\}$ , since clearly  $|S| = \kappa$ .

For each  $\xi < \lambda$  let us now define the set  $T_\xi \subset S$  as follows:

$$T_\xi = \cup\{(S_\xi \cap H_\alpha) \times \mu_\alpha : \alpha < \varrho\}.$$

Then we have  $|T_\xi| = \mu$  because  $|\{\alpha : H_\alpha \cap S_\xi \neq \emptyset\}| = \varrho$ . We claim that  $\{T_\xi : \xi < \lambda\}$  witnesses  $\Phi(\mu, \kappa, \lambda)$ .

Indeed, let  $A \subset S$  with  $|A| < \kappa$ . For each  $\alpha < \rho$  let  $B_\alpha$  denote the set of all first co-ordinates of the pairs that occur in  $A \cap (H_\alpha \times \mu_\alpha)$  and set  $B = \cup\{B_\alpha : \alpha < \varrho\}$ . Clearly, we have  $B \subset \kappa$  and  $|B| \leq |A| < \kappa$ , hence  $|\{\xi : |S_\xi \cap B| = \varrho\}| < \lambda$ .

Now, consider any ordinal  $\xi < \lambda$  with  $|S_\xi \cap B| < \varrho$ . If  $\langle \gamma, \delta \rangle \in (T_\xi \cap A) \cap (H_\alpha \times \mu_\alpha)$  for some  $\alpha < \varrho$  then we have  $\gamma \in S_\xi \cap B_\alpha$ , consequently  $H_\alpha \cap S_\xi \cap B \neq \emptyset$ . This implies that

$$W = \{\alpha : (T_\xi \cap A) \cap (H_\alpha \times \mu_\alpha) \neq \emptyset\}$$

has cardinality  $\leq |S_\xi \cap B| < \varrho$ . But for each  $\alpha \in W$  we have

$$|T_\xi \cap (H_\alpha \times \mu_\alpha)| \leq \varrho \cdot \mu_\alpha < \mu,$$

hence

$$T_\xi \cap A = \cup\{(T_\xi \cap A) \cap (H_\alpha \times \mu_\alpha) : \alpha \in W\}$$

implies  $|T_\xi \cap A| < \mu$  as well. But this shows that  $\{T_\xi : \xi < \lambda\}$  indeed witnesses  $\Phi(\mu, \kappa, \lambda)$ .  $\square$

Arhangel'skii has recently introduced and studied in [1] the class of spaces that are  $\kappa$ -compact for all uncountable cardinals  $\kappa$  and, quite appropriately, called them *uncountably compact*. In particular, he showed that these spaces are Lindelöf.

We recall that the spaces that are  $\kappa$ -compact for all uncountable *regular* cardinals  $\kappa$  have been around for a long time and are called linearly Lindelöf. Moreover, the question under what conditions is a linearly Lindelöf space Lindelöf is important and well-studied. Note, however, that a linearly Lindelöf space is obviously compact iff it is countably compact, i.e.  $\omega$ -compact. This should be compared with our next result that, we think, is far from being obvious.

**Theorem 6.** *Every linearly Lindelöf and  $\aleph_\omega$ -compact space is uncountably compact hence, in particular, Lindelöf.*

*Proof.* Let  $X$  be a linearly Lindelöf and  $\aleph_\omega$ -compact space. According to the (trivial) extrapolation property of  $\kappa$ -compactness that we mentioned in the introduction,  $X$  is  $\kappa$ -compact for all cardinals  $\kappa$  of uncountable cofinality. Consequently, it only remains to show that  $X$

is  $\kappa$ -compact whenever  $\kappa$  is a singular cardinal of countable cofinality with  $\aleph_\omega < \kappa$ .

But, according to theorems 4 and 5, we have  $\Phi(\aleph_\omega, \kappa, \kappa^+)$  and  $X$  is both  $\aleph_\omega$ -compact and  $\kappa^+$ -compact, hence theorem 2 implies that  $X$  is  $\kappa$ -compact as well.  $\square$

Arhangel'skii gave in [1] the following surprising result which shows that the class of uncountably compact  $T_3$ -spaces is rather restricted: Every uncountably compact  $T_3$ -space  $X$  has a (possibly empty) compact subset  $C$  such that for every open set  $U \supset C$  we have  $|X \setminus U| < \aleph_\omega$ . Below we show that in this result the  $T_3$  separation axiom can be replaced by  $T_1$  plus van Douwen's property  $wD$ , see e.g. 3.12 in [3]. Since uncountably compact  $T_3$ -spaces are normal, being also Lindelöf, and the  $wD$  property is a very weak form of normality, this indeed is an improvement.

**Definition 7.** A topological space  $X$  is said to be  $\kappa$ -concentrated on its subset  $Y$  if for every open set  $U \supset Y$  we have  $|X \setminus U| < \kappa$ .

So what we claim can be formulated as follows.

**Theorem 8.** *Every uncountably compact  $T_1$  space  $X$  with the  $wD$  property is  $\aleph_\omega$ -concentrated on some (possibly empty) compact subset  $C$ .*

*Proof.* Let  $C$  be the set of those points  $x \in X$  for which every neighbourhood has cardinality at least  $\aleph_\omega$ . First we show that  $C$ , as a subspace, is compact. Indeed,  $C$  is clearly closed in  $X$ , hence Lindelöf, so it suffices to show for this that  $C$  is countably compact.

Assume, on the contrary, that  $C$  is not countably compact. Then, as  $X$  is  $T_1$ , there is an infinite closed discrete  $A \in [C]^\omega$ . But then by the  $wD$  property there is an infinite  $B \subset A$  that expands to a discrete (in  $X$ ) collection of open sets  $\{U_x : x \in B\}$ . By the definition of  $C$  we have  $|U_x| \geq \aleph_\omega$  for each  $x \in B$ .

Let  $B = \{x_n : n < \omega\}$  be any one-to-one enumeration of  $B$ . Then for each  $n < \omega$  we may pick a subset  $A_n \subset U_{x_n}$  with  $|A_n| = \aleph_n$  and set  $A = \cup\{A_n : n < \omega\}$ . But then  $|A| = \aleph_\omega$  and  $A$  has no complete accumulation point, a contradiction.

Next we show that  $X$  is  $\aleph_\omega$  concentrated on  $C$ . Indeed, let  $U \supset C$  be open. If we had  $|X \setminus U| \geq \aleph_\omega$  then any complete accumulation point  $X \setminus U$  is not in  $U$  but is in  $C$ , again a contradiction.  $\square$

The following easy result, that we add for the sake of completeness, yields a partial converse to theorem 8.

**Theorem 9.** *If a space  $X$  is  $\kappa$ -concentrated on a compact subset  $C$  then  $X$  is  $\lambda$ -compact for all cardinals  $\lambda \geq \kappa$ .*

*Proof.* Let  $A \subset X$  be any subset with  $|A| = \lambda \geq \kappa$ . We claim that we even have  $A^\circ \cap C \neq \emptyset$ . Assume, on the contrary, that every point  $x \in C$  has an open neighbourhood  $U_x$  with  $|A \cap U_x| < \lambda$ . Then the compactness of  $C$  implies  $C \subset U = \cup\{U_x : x \in F\}$  for some finite subset  $F$  of  $C$ . But then we have  $|A \cap U| < \lambda$ , hence  $|A \setminus U| = \lambda \geq \kappa$ , contradicting that  $X$  is  $\kappa$ -concentrated on  $C$ .  $\square$

Putting all these theorems together we immediately obtain the following result.

**Corollary 10.** *Let  $X$  be a  $T_1$  space with property  $wD$  that is  $\aleph_n$ -compact for each  $0 < n < \omega$ . Then  $X$  is uncountably compact if and only if it is  $\aleph_\omega$ -concentrated on some compact subset.*
